Based on the provided video transcript, inheritance in Java follows the **"IS-A" concept**, where a specialized subclass inherits features from a generalized super class. This paradigm is primarily used to achieve **reusability**, code shareability, and maintainability.

Types of Inheritance Supported in Java

The sources specify that while various inheritance concepts exist, Java only supports a specific subset:

- **Single Inheritance:** A subclass inherits from only one super class.
- **Multiple Single Inheritance (Hierarchical):** Multiple subclasses are derived from a single common super class.
- **Multi-level Inheritance:** A subclass is derived from another subclass, creating multiple levels of hierarchy (e.g., a "Grandchild" inheriting from a "Child" which inherited from a "Parent").

Important Note: The sources explicitly state that Java **does not support multiple inheritance** (where one class inherits from multiple entities) or **hybrid inheritance**.

Difference Between 'super' and 'this' Keywords

The sources provide extensive detail on the **super** keyword but only mention **this** as a keyword used in previous contexts.

- **The super Keyword:** This keyword is used to refer to the immediate parent class and serves three main purposes:
    1. **Referencing Parent Variables:** It allows a subclass to access parent class instance variables, which is especially useful if the variable has been overridden in the subclass.
    2. **Invoking Parent Methods:** It is used to call a method from the parent class, helping to resolve namespaces if the subclass has a method with the same name.
    3. **Invoking Parent Constructors:** Using super() within a subclass constructor invokes the constructor of the parent class.
- **The this Keyword:** The provided source mentions that this is an important keyword similar to super, but it does not define its specific functionality in this lecture.

Information not found in the sources: While the sources do not detail the **this** keyword, it is generally understood in Java programming that while super refers to the parent class, this refers to the **current instance** of the class itself. You may want to independently verify this distinction in Java documentation.
